- Author: Vic Hargrave, includes links to other useful software/websites. Rest of the Story - Numerous fantastic features that are explained in this review. But before I do, let's take a look at some of the best XHTML editing tools on the market today. The field is crowded, and while there are some good programs out there -- including more expensive ones -- none of them really stands above the rest. With that in mind, here's a look at my top five choices -- as well as my number one. XHTML FAQ Lite Description: XHTML FAQ Lite is a simple, easy-to-use HTML editor. It's designed to allow you to create and maintain XHTML documents quickly and easily and even to take care of some HTML basics like comments and doctype declarations. It's perfect for the person who doesn't know HTML or is completely new to it, and it's also a great choice if you simply need some basic XHTML editing support but don't want to invest in more serious tools. The XHTML FAQ Lite is a direct descendant of the popular HTML FAQ Lite that we reviewed back in February. Of course, it's being updated to include greater support for XHTML and CSS coding and is being refined as well. The only major difference between the two versions is that it's now possible to set up the auto-complete capabilities to use the tag list from one tab (or any tab) and replace it with the tag list from the other (or other) tab. Pros: Simple tool that offers a lot for little money. Great source of information for new users. Good for people who don't know much about XHTML. Provides free maintenance. Cons: Doesn't save automatically. No easy way to switch from HTML to XHTML or vice versa. DigiTool Description: DigiTool is a simple, easy-to-use HTML editor. It's designed to allow you to create and maintain HTML documents quickly and easily and even to take care of some HTML basics like comments and doctype declarations. It's perfect for the person who doesn't know HTML or is completely new to it, and it's also a great choice if you simply need some basic HTML editing support but don't want to invest

A tutorial explaining how to browse the web, receive pages from web servers, and send data to web servers using the HTTP protocol. introduction Every time you load a web page into a browser, you are using a special TCP/IP (Transmission Control Protocol/Internet Protocol) socket. This socket works over the Internet, and allows us to connect to a web server, transfer data between the two computers, and receive data back from the web server. Web browsers use the HTTP protocol to communicate with the web servers on the World Wide Web. In order for our web browser to get information from web servers, it must use the HTTP protocol. Web browsers use the HTTP protocol to access the Internet. The web browsers must use the HTTP protocol to obtain the actual content from a web server. The HTTP protocol is used to get web page content, files or data. It is used by web servers to send information to web browsers. HTTP uses port 80 on the TCP/IP stack. To access web pages, web browsers use the protocol established by host machines to connect to the Internet. This host is called the HTTP server. It also establishes a connection with the host TCP/IP stack where the web browser resides. This connection is used to send data from the server to the browser. The client requests the information. The server provides the information. There are many different types of HTTP servers. For this tutorial, we will learn how to use the Apache HTTP Server, a commonly used web server for Windows and Unix based operating systems.
